

My Prompts

1 Create RAG file

Analyze all Java **source** files **in** this project and produce a RAG reference document saved as documents/AgentCodeContext.md.

This project is a Forth compiler written **in** Java. Forth is a stack-based language **where** named procedures are called "**verbs**" (or "**words**"), stored **in** a "**dictionary**", and executed by manipulating a data stack.

Structure the document with the following sections:

1. Forth Concepts Glossary

Brief definitions of domain terms used **in** the code: verb, dictionary, stack, token, definition, constant, variable, word execution.

2. Class Inventory

For each class include:

- Package and class name
- Single-sentence responsibility
- Key public methods with their purpose
- Important fields that carry state

3. Class Relationships (UML-style)

Describe all relationships between classes:

- Inheritance (extends / implements)
- Composition (owns an instance of)
- Dependencies (uses / calls into)

Use a format like: `ClassA --> ClassB : dependency reason`

4. Compiler Pipeline (Execution Flow)

Trace the end-to-end flow **for** each of these scenarios:

1. A line of Forth input is parsed and executed
2. A new verb definition is created and stored **in** the dictionary
3. A previously defined verb is looked up and executed

5. Extension Guide

For each of these common change tasks, list **which** classes to modify and **in** what order:

- Adding a new built-in verb
- Adding a new variable/constant **type**
- Changing how input lines are tokenized

Keep section headers consistent so the document can be split into chunks **for** vector embedding.

There are no databases **in** this project – **do** not reference or suggest any.
